TITLE: Concerning the nature of optical absorption of polycrystalline films of cadmium sulfide

SOURCE: IVUZ. Fizika, no. 3, 1964, 139-143

TOPIC TAGS: thin film, sublimated film, absorption spectrum, excitation spectrum, cadmium sulfide

ABSTRACT: This is a continuation of earlier work by some of the authors (K. V. Shalimova, I. V. Karpenko, NDVSh, Radiotekhnika i elektronika, v. 2, 233, 1958; K. V. Shalimova, T. S. Travina, L. L. Golik, DAN SSSR v. 138, 1, 1961). In the present work, new data are given for thin layers of cadmium sulfide containing different amounts of cadmium atoms in excess of stoichiometric composition. The methods of preparing the films and the test procedure are briefly

Card 1/4

ACCESSION NR: AP4041854

described. The experiments on absorption spectra have shown that if the layer is deposited from vapor of the initial substance in which there are no free cadmium atoms or else there is an excess of sulfur atoms, then the absorption of the compounds is very small in the visible region. Such layers were prepared by sublimation without dissociation of the sulfide. The strong absorption of the visible region of the spectrum observed in some cases can be greatly reduced by heating the samples in sulfur vapor. Results are described of the absorption spectra of the films, as functions of the medium in which the initial powder was sputtered, its sublimation temperature, and the heating of the substrate on which the sample was deposited. The optical density of the compounds obtained by simultaneous sublimation of cadmium sulfide and metallic cadmium is examined, and also the influence of heat treatment of the sputtered layers in sulfur vapor. On the basis of the obtained experimental data it is concluded that the absorption of cadmium sulfide in the visible or near ultraviolet regions has an impurity character. The investigations of films produced by different methods gave practically the same results.

Card 2/4

ACCESSION NR: AP4041854

which can be summarized as follows. 1. Strong absorption of CdS in the visible and the near ultraviolet region is observed only in the samples activated with cadmium. 2. Two maxima are observed in the region of impurity absorption (320 and 420 millimicrons), if the substances are made on specially heated substrates. If the substrate is heated to 450C, the maxima are located at 380 and 490 millimicrons. This indicates that the cadmium impurity in the sulfide lattice has two excitation levels. 3. In the far ultraviolet the cadmium sulfide films have a strong absorption band with a maximum at 230 millimicrons which can be shown to be due to intrinsic absorption of the cadmium sulfide. The value of the absorption coefficient ( $10^5 - 10^6 \text{ cm}^{-1}$ ) indicates that the absorption is due to direct optical transitions of the electron film in the valence band to the conduction band. Consequently, the width of the forbidden band for the direct optical transitions should be 5.3 eV. Orig. art. has 4 figures.

electrical fields

SOURCE: Fizika tverdogo tela, v. 8, no. 9, 1966, 2660-2663

TOPIC TAGS: optical absorption, absorption coefficient, cadmium, cadmium  
sulfideABSTRACT: A study of CdS monocrystals ( $\sim 10-20 \mu$  in thickness), at the temper-  
ature of liquid nitrogen, reveals an oscillating component arising in a strong electric  
field, which is in spectral dependence on the coefficient of absorption. The period  
of oscillations  $T$  was found to be equal to  $\frac{2\pi h}{eEd}$  (where  $E$  is field intensity and  $d$ is the lattice constant in the direction of the field). If the scattering of carriers is  
taken into account, difficulties are encountered in explaining this phenomenon in

Title : Fattening of Cattle on Pasture and by Food Supplementation  
(Narul i etkemi krugnogo reperage skotu)

Orig Pub : S. kh. Kazakhstan, 1957, № 5, 25-27

Abstract : In Western Kazakhstan, the fattening of cattle on pasture is combined with fattening in dry lot. After being pastured in the fall for 50-60 days, the cattle were finished in dry lot with roughage, succulent foods and concentrates; fattening before pasturing was also resorted to. The experience showed that pasturing and fattening, each for 40 days, and for young cattle, each for 50-100 days, is sufficient.

**2850. REMARKS CONCERNING THE PATHOGENESIS OF AMNIOTIC FLUID**

EMBOLISM - Poznámky k patogenéze embolizace plodového vodovodu; Stopekova  
M., Ust. Patol. Anat. Lek. Fak., Univ. Komenskeho, Košice - BRATISL.  
LEK. LISTY 1958, 38(II) 8 (466-473) Ilus. 5

An analysis of a case of amniotic fluid embolism in a 35-year-old V-paria is given. Morphological study was made of the whole foetus and the foetal membranes; no surgical intervention had been performed. The study of serial histological preparations of the uterus revealed the presence of amniotic fluid in the uterine veins practically at all levels examined. Neither in the blood vessels of the placenta nor in the vessels of the foetus could embolism of amniotic fluid be demonstrated. It seems therefore very likely that the uterine veins are the only pathways through which the amniotic fluid passes from the amniotic sac into the systemic circulation or into the lungs, be it through large or interposed minute venous sinuses. The rate at which the first symptoms of embolism with amniotic fluid appear is in direct proportion with the amount of amniotic fluid present in the amniotic sac at the given moment, with the number and capacity of opened veins in the uterus, as well as with the tonic activity of the uterus. The quicker the symptoms of the embolism with amniotic fluid appear, the greater the quantity of amniotic fluid that penetrates into the veins of the uterus, and vice versa. A rapid diagnosis of amniotic fluid embolism could be made by polaroscopic examination of frozen sections of unfixed lung.

*STOPKA, VIKTOR*

77 Properties of Sorel cements. OTAKAR KALATOREK AND VIKTOR STOPKA - *Sintez A.*, 5 [10] 431-30 (1954). The properties of Sorel cements between setting, volume constancy, and moisture content of Sorel cements with 5 different kinds of feed (amorphous) microcrystalline magnesites were investigated in the presence of Mg carbonate, Mg hydroxide, and lime. The setting velocity increases with time; its course is characteristic for each kind magnesite and depends on the temperature of calcination, fineness of grinding, foreign constituents, and concentration of the  $MgCl_2$  solution. The temperature maximum obtainable depends on the length of storage of the magnesite, as hydration takes place slowly. Calcined magnesites having a high temperature maximum reach it faster and set faster. The rapidity of the water exchange with the surrounding atmosphere influences volume constancy considerably and runs parallel with the linear expansion of Sorel cements. The 28 day values for tensile strength are in part lower than the 7-day values, which indicates a tendency to swell. With concentrated  $MgCl_2$  solution, lime recognized to be harmful gives basic Ca chloride which makes the hardened Sorel cement damp, makes it swell, and forms efflorescence. Addition of Mg sulfate (up to 5% maximum) to the  $MgCl_2$  solution of 22° fels does not transform the actually existing lime in swelling Ca sulfate; no  $Ca(OH)_2$  is produced, and the Sorel cement is improved. M.H.A.

TITLE: Effect of Organic and Mineral Fertilizers on the Growth of Pine Cultures (Vliyaniye organo-mineral'nykh udobreniy na rast sosnovykh kul'tur)

PERIODICAL: Dopovidi Akademii Nauk Ukrains'koj RSR, 1950, # 1, pp 111-113  
(USSR)

ABSTRACT: The author describes the results of investigations carried out by the Institute of Forestry (Instytut lisu) of the Ukrainian Academy of Sciences in the Volyn' region of the Ukraine. The results show the effect of organic and mineral fertilizers on the growth of seven-year-old pines on former arable soil under conditions of the Foles'ye. It has been proved that the principal cause of the poor growth and condition of the pine on former arable sandy soil was the paucity of soil nutrients, especially nitrogen. The application of fertilizers (compost, marl, ammonium nitrate) was found to be highly effective, as is evident from the table and graphs included in the article. The article contains 1 table, 2 graphs and 1 Russian reference.

847. RESEARCHES ON THE POLLUTION OF SURFACE WATERS WITH OIL RESIDUES. Observații asupra impurificării apelor de suprafață cu reziduuri petrolieri. (Comunicare preliminara). Stoilescu T. and Obreja N.

IGIENA (București) 1956, 1/2 (23-32) Graphs 1 Tables 3

The protection of rivers against pollution with oil residues represents an important sanitary problem in the Rumanian People's Republic. Chemical and bacteriological determinations made on 3 rivers impurified by oil residues have been carried out in order to establish the degree of pollution of these surface waters. The method of S. D. Zamislova used for the chemical determination proved to be the most suitable. Some parts of the rivers contained oil residues exceeding 0.1 mg./l., the maximum limit admitted in surface waters in Rumania. Considering that Rumanian oil contains an unimportant amount of sulphurous substances the authors' opinion is that the actual limit is too low. A concentration of 0.3 mg./l. is proposed as a

697

maximum admitted in order to test this proposal.

"Presence of Coagulase-Positive Staphylococci in Water from a  
Swimming Pool."

Bucharest, Microbiologia, Parazitologia, Epidemiologia, Vol 11,  
No 3, May-Jun 66, pp 273-279.

Abstract [Authors' English summary modified]: On the occasion of  
a study of a group of 7 to 14-year old schoolchildren who regularly  
used a particular swimming pool, the authors found that 51.3 per-  
cent of the 193 children tested were healthy carriers of coagulase-  
positive staphylococci. The authors suggest that this very high  
percentage is due to the water in the pool, where there is an  
increased density of such germs whenever the residual chlorine  
falls to below 0.1 milligrams per liter.

Includes 7 tables and 7 references, of which 2 Rumanian and  
5 English-language. -- Manuscript submitted 26 September 1964.

Measurement of Deformation on Rotating Devices With Increased Accuracy (Izmereniye deformatsii na vrashchayushchikhsya ustroystvakh s povyshennoy tochnost'yu)

PERIODICAL:

Zavodskaya Laboratoriya, 1959, Vol 25, Nr 6, pp 755-756 (USSR)

ABSTRACT:

A new wiring diagram for current collectors (Fig) for the purpose of eliminating errors of measurement occurring with current collectors is described here. This new circuit permits the use of current collectors with variable transition resistance, 100 times higher than in ordinary ones (up to 50 ohm). The current used for the bridge supply as well as the transient current are on two different current collector rings and are outside the circuit of the galvanometer. A comparison of the accuracy of measurement of the diagram described with that hitherto employed shows that an error of measurement of 200% according to the old diagram amounts to only 5% when measured by the new diagram. Current collectors consisting of seven rings with graphite contact brushes were used for the experiments. There is 1 figure.

TITLE: Highly Sensitive Pressure Pickups Made of Organic Glass

PERIODICAL: Izmeritel'naya tekhnika, 1960, No. 10, p. 33

TEXT: The author describes a tension-type, diaphragm-operated pickup designed by him for measuring pressure in liquids and in pulsating streams. These instruments are used primarily for measuring water pressures. Two working pickups are glued on to the diaphragm and two compensation pickups on to the basis of the casing by means of acetone-celluloid glue No. 11. The shell with the casing is glued together by means of a 2-3% solution of organic glass in dichloro ethane. Case and diaphragm are made of organic glass, the modulus of elasticity of which is 210 kg/cm<sup>2</sup>. No seeping through of water was observed in such pickups. For measuring small values of pressure and pulsation in streams on small surfaces, a cap of organic glass with an opening similar to the investigated surface, is welded on to the pickup. The liquid reaches the diaphragm through this opening. Such pickups show a high degree of

Card 1/2

sensitivity. The author used pickups with a diaphragm thickness of from 0.4 to 1mm for measuring pressure and pulsation in water turbine models. The pickup has linear characteristics and good sealing. Pressures up to 10 mm water column could be measured by means of a bifilar oscillograph of the type ST-24 (ST-24) (without amplifier). There is 1 figure.

TITLE: Concerning Two Stages of the Critical Condition of Cavitation

PERIODICAL: Energomashinostroyeniye, 1961, No.4, pp.21-22

TEXT: Cavitation investigations made in recent years have shown that under most conditions a water turbine is subject to cavitation and its condition is often not what would be expected from cavitation tests on models. This difference has been suspected for a long time but there was no objective method of investigating cavitation on operating turbines and the conclusions were based on wear or noise. The cause was sought in inaccuracies of modelling of cavitation. Quite apart from the conditions of modelling cavitation there exists another equally important cause of error in the procedure of calculating transfer of cavitation from the model to the full-scale machine. This is the presence of two stages of development of cavitation which are not reflected in the cavitation characteristics. This article considers the causes of the formation of two-stages of cavitation and acoustic methods of

Card 1/6

Concerning Two Stages of ...

detecting them. Cavitation effects in turbines are characterized by loss of power and efficiency, erosive wear, vibration and noise. These effects take place at different stages of cavitation, thus the efficiency falls off before there is appreciable vibration. It is usually considered that loss of efficiency or power is the most dangerous condition in water turbines. Until this occurs the machine operates quietly without vibration or noise. The cavitation conditions at which the efficiency characteristics alter is termed the critical condition of cavitation. The coefficient that governs this condition of cavitation is termed the critical cavitation coefficient and it is found by plotting curves of efficiency as function of cavitation coefficient. Fig. 1 shows three typical curves of efficiency and referred speed as function of cavitation coefficient. The curves obtained by the power method do not reveal the process of development of cavitation in the machine but only the initial change in efficiency. However, the top and bottom pairs of curves show the development of two stages of critical cavitation corresponding to two critical coefficients of cavitation. The

Card 2/6

2016\*

Concerning Two Stages of ...

7/14/61/000/004/003/006  
E194/E435

first stage corresponds to change of conditions of flow of liquid over the profiles which may even increase the efficiency, in the second stage the efficiency always falls. The value of the first critical coefficient cannot always be found by the energy method of determination. Stroboscopic observation through a transparent casing showed that there are machine conditions when cavitation is well developed but it is still not revealed by the energy method. Several theories have been offered to explain the nature of the two values of cavitation coefficient. It is supposed that the first stage of the critical condition of cavitation is associated with the appearance of cavities at individual points on the blade profile. The second stage corresponds to developed cavitation of the main flow and approaches loss of flow continuity. The intensity of noise in a full-scale machine is much greater than in models. This means that in the full-scale machine the first cavitation coefficient sets in earlier than in the model and is more marked. This is confirmed by the cavitation curves plotted in Fig. 2 for turbines of 1 and 0.25 m diameter. It is considered important to determine both stages of cavitation on turbine models even if they have no influence on the power characteristics of the

Card 3/6

W

20168

Concerning Two Stages of ...

S/114/61/000/004/003/006  
E194/E435

machine. An acoustic method of determining the critical condition of cavitation is then described. The procedure has been described by the same author in an article in the journal Elektricheskiye Stantsii, 1957, No.8. It is based on the fact that the origination of cavitation is associated with the formation of vapour-gas bubbles which collapse and cause a noise. As cavitation develops, the intensity of pressure impulses increases. Experiments have shown that in water turbines and pumps cavitation bubbles begin to form at the same time as noise of ultrasonic frequency. The development of cavitation coincides with increase in the amplitude of ultrasonic vibrations measured on a frequency analyser. The bubbles are not only the source of sound but also form a sound absorbing medium through which the sound must pass. Absorption of the sound depends on the ratio of the dimensions of the bubbles to the wavelength of the sound and absorption is most marked if the sound frequency coincides with the natural frequency of the bubbles. When the critical condition of resonance occurs, there is a marked increase in the formation of vapour-gas bubbles, the flow conditions and the efficiency are altered. This bubble evolution is very extensive

Card 4/6

2016\*

Concerning Two Stages of ...

3/114/61/CCC/004/005/006  
3194/3455

and the layer of bubbles strongly absorbs the sounds passing through it. Experiments have shown that if a narrow band of frequencies is separated from the total noise, preferably in the ultrasonic range, the drop of noise intensity beyond a certain minimum corresponds to the critical condition of cavitation. This acoustical method is a sensitive means of determining the critical condition of cavitation even if it does not influence the power characteristics of the machine. It is concluded that the existing method of studying cavitation from the power characteristics does not reflect the relationship between the cavitation condition of the blades and the machine efficiency. This method only demonstrates the changes in efficiency caused by cavitation in the actual body of the flow. By the acoustics method two critical conditions of cavitation may be determined so giving fuller information about cavitation conditions. There are 4 figures and 5 Soviet references.
